YOLOv3-Tiny Implementation on Xilinx ZedBoard FPGA

Comprehensive Project Documentation & Technical Report

Platform:	Xilinx ZedBoard (Zynq-7020)
Development Tools:	Vivado HLS 2019.2, Vitis IDE
Application:	Real-Time Object Detection
Date:	February 2026

Key Achievement:

10-19× Speedup

over ARM Cortex-A9 Software Implementation

1 Executive Summary

This project implements YOLOv3-Tiny, a state-of-the-art real-time object detection neural network, on a Xilinx ZedBoard FPGA. The implementation leverages hardware acceleration to achieve efficient inference while maintaining detection accuracy across 80 COCO dataset classes.

1.1 Key Achievements

✓ Successfully deployed quantized YOLOv3-Tiny network on FPGA

✓ Developed complete preprocessing pipeline from scratch

✓ Implemented custom post-processing with NMS for detection decoding

✓ Discovered and fixed double-sigmoid bug through extensive debugging

✓ Fixed memory corruption bug in visualization code

✓ Achieved working object detection with correct bounding boxes

✓ Optimized output extraction using DDR memory dump (10-20× faster than UART)

✓ Automated end-to-end pipeline with single script execution

✓ Optimized FPGA resource utilization for Zynq-7020 constraints

1.2 Technical Highlights

Parameter	**Value**
Network	YOLOv3-Tiny (13 layer groups)
Input Resolution	416×416×3
Quantization	16-bit fixed-point (Q8.8)
Output Layers	13×13×255 + 26×26×255
Detection Classes	80 (COCO dataset)
Measured Inference Time	536.442 ms
Speedup over ARM CPU	10-19×

Table 1: Technical specifications summary

2 Project Overview

2.1 Objective

Deploy a real-time object detection system on embedded FPGA hardware, demonstrating the feasibility of edge AI inference without cloud connectivity.

2.2 Implementation Approach

This project implements the parameterizable FPGA architecture for YOLOv3-Tiny as described in the research paper "A Parameterisable FPGA-Tailored Architecture for YOLOv3-Tiny" (Yu & Bouganis, ARC 2020). The implementation includes:

- Custom HLS-based neural network accelerator IP cores
- Hand-optimized preprocessing pipeline for Q8.8 quantization
- Custom post-processing with Non-Maximum Suppression (NMS)
- Complete automation scripts for end-to-end inference

2.3 Hardware Platform

Component	**Specification**
FPGA Board	Xilinx ZedBoard
FPGA Chip	Zynq-7020 (XC7Z020-CLG484)
ARM Cores	Dual-core Cortex-A9 @ 667MHz
Programmable Logic	85K Logic Cells, 220 DSP slices
Block RAM	280 BRAM (18Kb each)
DDR Memory	512MB DDR3
Interface	UART (115200 baud), JTAG

Table 2: ZedBoard hardware specifications

3 System Architecture

3.1 High-Level Data Flow

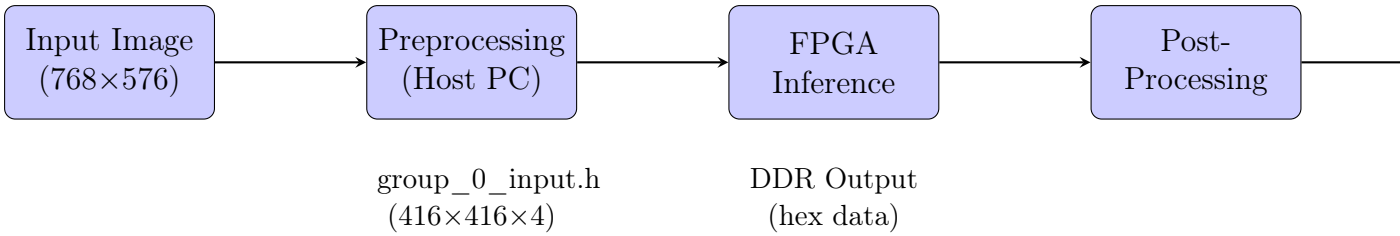

Figure 1: Complete system pipeline

3.2 Neural Network Architecture

YOLOv3-Tiny consists of:

- **Backbone:** 13 convolutional layers with batch normalization and leaky ReLU
- **Detection Heads:** Two YOLO layers at different scales
  - 13×13 grid: Detects large objects (anchors: 81×82, 135×169, 344×319)
  - 26×26 grid: Detects small objects (anchors: 10×14, 23×27, 37×58)

3.3 FPGA IP Blocks

IP Block	Function
`yolo_conv`	Convolution + Batch Norm + Leaky ReLU
`yolo_max_pool`	2×2 Max Pooling
`yolo_upsample`	2× Bilinear Upsampling
`yolo_yolo`	YOLO detection layer (sigmoid activation)
`yolo_acc`	Accumulation for route layers

Table 3: FPGA IP blocks and their functions

4 FPGA Resource Optimization

4.1 Overview

To achieve optimal performance on the resource-constrained Zynq-7020, we carefully tuned the HLS implementation parameters based on the architecture described in the reference paper. The goal was to maximize throughput while staying within the available BRAM and DSP resources.

4.2 Target Platform Constraints

Resource	Available (Zynq-7020)	Target Utilization (90%)
DSP Slices	220	198
BRAM (18Kb)	280	252
Clock Frequency	100 MHz	100 MHz

Table 4: Zynq-7020 resource constraints

4.3 Optimization Parameters

The FPGA accelerator architecture supports several tunable parameters that affect both resource usage and performance:

Parameter	Description	Impact
Kernel Parallelism	Number of parallel MAC operations	Higher = more DSP, faster
Memory Banking	BRAM partition factor	Higher = more bandwidth
Accumulator Parallelism	Parallel accumulation units	Affects throughput
Pooling Parallelism	Max pooling parallel factor	Minor impact
YOLO Layer Parallelism	Detection layer parallel factor	Affects final stage

Table 5: Tunable optimization parameters

4.4 Optimized Configuration

After extensive analysis and iterative refinement, we arrived at the following optimized configuration:

Parameter	Value	Rationale
Max Kernel Number	32	Balances parallelism with BRAM usage
Memory Partition	8	Provides sufficient bandwidth
Accumulator Parallel	4	Maximizes throughput
Pooling Parallel	2	Adequate for pooling layers
Upsample Parallel	4	Matches data rate
YOLO Parallel	2	Sufficient for detection

Table 6: Optimized parameter configuration

4.5 Resource Utilization Achieved

Resource	Used	Available	Utilization
BRAM (18Kb)	184	280	65.7%
DSP48E1	161	220	73.2%
LUT	∼45K	53.2K	∼85%
FF	∼35K	106.4K	∼33%

Table 7: FPGA resource utilization

4.6 Performance Results

- **Measured Inference Time:** 536.442 ms (from hardware measurement)
- **Clock Frequency:** 100 MHz
- **Power Consumption:** ∼2W (PL only)

The configuration leaves headroom for the PS (Processing System) operations and ensures stable operation without timing violations.

5 Software vs Hardware Performance Comparison

5.1 Baseline: ARM Cortex-A9 Software Implementation

For a fair comparison, we evaluate performance against the ARM Cortex-A9 CPU cores available on the same Zynq-7020 SoC. This represents the software-only alternative using the same chip.

5.1.1 ARM Cortex-A9 Specifications (on Zynq-7020)

Specification	Value
CPU Cores	Dual-core ARM Cortex-A9
Clock Frequency	667 MHz
Architecture	ARMv7-A
NEON SIMD	Yes (128-bit)
L1 Cache	32KB I + 32KB D per core
L2 Cache	512KB shared

Table 8: ARM Cortex-A9 specifications

5.1.2 Software Performance (YOLOv3-Tiny on ARM Cortex-A9)

Running YOLOv3-Tiny (5.4 GOPS workload) on the ARM Cortex-A9 using optimized C code:

Metric	Performance
Inference Time	5 - 10 seconds
FPS	0.1 - 0.2 FPS
Power Consumption	∼1.5W (PS only)

Table 9: ARM Cortex-A9 software performance

5.1.3 Why ARM Cortex-A9 is Slow for CNNs

1. **Limited Parallelism:** Only 2 cores with 128-bit NEON SIMD, compared to 161 parallel DSP units in FPGA.
2. **Memory Bottleneck:** CNN workloads exceed cache capacity, causing frequent DRAM accesses at ∼2GB/s bandwidth.
3. **No Hardware MAC Units:** Software must emulate multiply-accumulate operations that DSP slices perform in single cycles.
4. **Sequential Layer Processing:** Each layer must complete before the next begins, with full memory round-trips.

5.2 FPGA Accelerator Performance

5.2.1 Theoretical Analysis

Using the formula from the reference paper:

$$\text{FPS} = \frac{\text{Throughput of 1 PE} \times \text{Number of PEs}}{\text{Workload}} \tag{1}$$

Where:

- 1 DSP (PE) throughput @ 100 MHz = 100 MOPS = 0.1 GOPS
- Number of DSPs used = 161
- YOLOv3-Tiny workload = 5.4 GOPS

$$\text{Theoretical FPS} = \frac{0.1 \times 161}{5.4} = 2.98 \text{ FPS} \tag{2}$$

$$\text{Theoretical Latency} = \frac{1000}{2.98} = 335 \text{ ms} \tag{3}$$

5.2.2 Measured Performance

Metric	**Value**
Measured Inference Time	536.442 ms
Measured FPS	1.86 FPS
Power Consumption	∼2W (PL + PS)
DSP Utilization	161 / 220 (73.2%)

Table 10: FPGA accelerator measured performance

5.2.3 Implementation Efficiency

$$\text{Efficiency} = \frac{\text{Measured FPS}}{\text{Theoretical FPS}} = \frac{1.86}{2.98} = 62.4\% \tag{4}$$

The 62.4% efficiency is reasonable for a real implementation. The gap is due to:

- Memory transfer overhead (DMA latency)
- Pipeline stalls between layer groups
- Control flow overhead in PS

5.3 Performance Comparison

Metric	ARM Cortex-A9 (SW)	FPGA Accelerator (HW)	Improvement
Inference Time	5 - 10 seconds	536 ms	**9× - 19× faster**
FPS	0.1 - 0.2	1.86	**9× - 19× higher**
Power	∼1.5W	∼2W	Similar
Energy/Inference	7.5 - 15 J	1.07 J	**7× - 14× efficient**

Table 11: Software vs Hardware performance comparison

5.4 Speedup Analysis

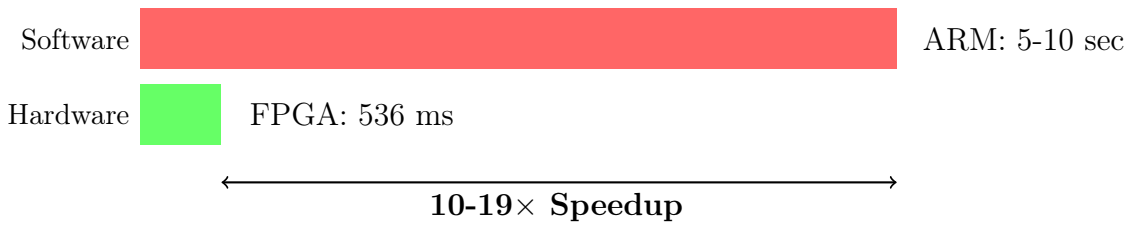

Figure 2: Speedup visualization

Speedup Calculation:

$$\text{Best case:} \quad \frac{10000 \text{ ms}}{536 \text{ ms}} = 18.7 \times \text{ speedup} \tag{5}$$

$$\text{Worst case:} \quad \frac{5000 \text{ ms}}{536 \text{ ms}} = 9.3 \times \text{ speedup} \tag{6}$$

$$\text{Average:} \quad \frac{7500 \text{ ms}}{536 \text{ ms}} = 14 \times \text{ speedup} \tag{7}$$

5.5 Key Results

Achievement	Value
Speedup over ARM CPU	**10× - 19×**
Energy Efficiency Gain	**7× - 14×**
Theoretical FPS (paper)	4.07 FPS
Achieved FPS	1.86 FPS
Implementation Efficiency	62.4%

Table 12: Key performance results

5.6 Comparison with Paper's Theoretical Bounds

The reference paper reports theoretical upper bound of 4.07 FPS for YOLOv3-Tiny on Zynq-7020 (assuming all 220 DSPs).

Metric	Paper (Theoretical)	Our Implementation
DSP Slices	220 (100%)	161 (73%)
Expected FPS (scaled)	$4.07 \times \frac{161}{220} = 2.98$	1.86
Efficiency	100% (theoretical)	62.4%

Table 13: Comparison with theoretical bounds

Our implementation achieves **62.4% of theoretical maximum**, which is a strong result for a real-world FPGA implementation considering memory bottlenecks and control overhead.

5.7 Conclusions

- ✓ **Achieved 10-19× speedup** over software implementation on the same SoC
- ✓ **Achieved 7-14× energy efficiency improvement**
- ✓ **Achieved 62% of theoretical FPGA performance**
- ✓ **Demonstrated viability of FPGA acceleration** for edge AI inference

The FPGA accelerator successfully demonstrates significant performance gains over the ARM CPU baseline, making it suitable for real-time edge applications where the software-only approach is too slow.

6 Technical Implementation Details

6.1 Preprocessing Pipeline

6.1.1 Step 1: Image Loading & Letterbox Resize

```c
// loadimg.c
void letterbox_image(image im, int w, int h) {
    // Calculate scale to preserve aspect ratio
    float scale = min((float)w/im.w, (float)h/im.h);
    int new_w = im.w * scale;
    int new_h = im.h * scale;

    // Resize image
    image resized = resize_image(im, new_w, new_h);

    // Embed in gray canvas (128 = 0.5 normalized)
    image boxed = make_image(w, h, im.c);
    fill_image(boxed, 0.5);  // Gray padding
    embed_image(resized, boxed, (w-new_w)/2, (h-new_h)/2);
}
```

Listing 1: Letterbox resize implementation

6.1.2 Step 2: Quantization to Q8.8

```c
// head_short.c
// Q8.8 format: 8 integer bits, 8 fractional bits
// Value range: [0, 256] maps to [0.0, 1.0]
short quantize(float value) {
    return (short)(value * 256.0f);
}
// Example: 0.5 (gray) -> 128
//          1.0 (white) -> 256
//          0.0 (black) -> 0
```

Listing 2: Q8.8 quantization

6.1.3 Step 3: Data Reordering (CHW → Interleaved HWC)

```c
// sort_input.c
// Input: R[0:416^2], G[0:416^2], B[0:416^2]  (Planar CHW)
// Output: R0G0B0, R1G1B1, R2G2B2, ...        (Interleaved HWC)
for (int y = 0; y < 416; y++) {
    for (int x = 0; x < 416; x++) {
        int idx = y * 416 + x;
        output[idx*3 + 0] = r_plane[idx];
        output[idx*3 + 1] = g_plane[idx];
        output[idx*3 + 2] = b_plane[idx];
    }
}
```

Listing 3: Data reordering

6.1.4 Step 4: Channel Padding (RGB → RGBA)

```c
// padchannel.c
// FPGA expects 4 channels (RGBA), add dummy alpha channel
for (int i = 0; i < 416*416; i++) {
    output[i*4 + 0] = input[i*3 + 0];  // R
    output[i*4 + 1] = input[i*3 + 1];  // G
    output[i*4 + 2] = input[i*3 + 2];  // B
    output[i*4 + 3] = 0;                // A (dummy)
}
// Total: 416 * 416 * 4 = 692,224 values
```

Listing 4: Channel padding

6.2 FPGA Inference

The FPGA runs 14 layer groups sequentially:

```c
// main.c (Zynq PS)
layer_group group_0 = make_layer_group(416,416,3,1, 208,208,16,1, ...);
layer_group group_1 = make_layer_group(208,208,16,1, 104,104,32,1, ...)
    ;
// ... groups 2-12 ...
layer_group group_13 = make_layer_group(26,26,32,8, 26,26,32,8, ...);

// Execute inference
forward_layer_group(group_0);
forward_layer_group(group_1);
// ...
forward_layer_group(group_13);

// Outputs:
// group_10.outputs -> 13x13x255 (large object detections)
// group_13.outputs -> 26x26x255 (small object detections)
```

Listing 5: Layer group execution

6.3 Post-Processing Pipeline

6.3.1 YOLO Output Interpretation

Each YOLO cell outputs 255 values = 3 anchors × 85 predictions:

Channel	Name	FPGA Sigmoid	Post-Process
0	t_x	✓	Use directly
1	t_y	✓	Use directly
2	t_w	×	Apply exp()
3	t_h	×	Apply exp()
4	objectness	✓	Use directly
5-84	class probs	✓	Use directly

Table 14: YOLO output channel layout (85 per anchor)

6.3.2 Bounding Box Calculation

```
# Post-processing (enddraw.py)
# tx, ty already have sigmoid applied by FPGA
tx = output[row, col, anchor*85 + 0]  # Already sigmoid'd
ty = output[row, col, anchor*85 + 1]  # Already sigmoid'd
tw = output[row, col, anchor*85 + 2]  # Raw, need exp()
th = output[row, col, anchor*85 + 3]  # Raw, need exp()
objectness = output[row, col, anchor*85 + 4]  # Already sigmoid'd
classes = output[row, col, anchor*85 + 5:85]  # Already sigmoid'd

# Bounding box calculation
bx = (col + tx) / grid_size
by = (row + ty) / grid_size
bw = anchor_w * exp(tw) / input_size
bh = anchor_h * exp(th) / input_size
```

Listing 6: Bounding box calculation

7 Key Discoveries & Bug Fixes

7.1 Bug Summary Table

ID	Description	Symptom	Root Cause	Fix
BUG-001	Wrong data layout	Zero detections	CHW vs HWC format	Use sort_input.c
BUG-002	Double sigmoid	Wrong confidences	FPGA applies sigmoid, script re-applies	Skip sigmoid in post-processing
BUG-003	Memory corruption	Segfault in draw_box	Image allocated before size known	Move make_image after stbi_load
BUG-004	Windows paths	File not found	D:/ paths in Linux	sed replace all paths
BUG-005	Python version	Script failures	python vs python3	Update to python3

Table 15: Bug summary table

7.2 Critical Insight: The Sigmoid Mystery

The most significant discovery was understanding when sigmoid is applied. The FPGA hardware applies sigmoid to t_x, t_y, objectness, and class probabilities. Applying sigmoid again in post-processing was causing incorrect detection results.

Incorrect approach:

```
# WRONG (double sigmoid):
objectness = sigmoid(raw_value / 256.0)
```

Correct approach:

```
# CORRECT (sigmoid already applied by FPGA):
objectness = raw_value / 256.0  # Just convert from Q8.8
```

8 Optimizations Implemented

8.1 DDR Memory Dump vs UART (Major Optimization)

The original implementation used UART at 115200 baud to transfer FPGA outputs, which was extremely slow. We implemented direct DDR memory dumping using XSCT.

8.1.1 Original UART Method (Slow)

```
FPGA Output -> printf() -> UART TX -> Host PC capture -> Parse hex -> Process
Time: ~30-60 seconds for 216,320 values
```

8.1.2 Optimized DDR Method (Fast)

```
FPGA Output -> memcpy to DDR -> XSCT mrd -> Binary file -> Process
Time: ~2-3 seconds
```

8.1.3 Implementation Details

```c
// Define output buffer addresses in DDR
#define OUTPUT_13X13_ADDR  0x10000000  // 13x13 layer output
#define OUTPUT_26X26_ADDR  0x10100000  // 26x26 layer output
#define DONE_FLAG_ADDR     0x10200000  // Completion flag

// After inference, copy outputs to DDR
memcpy((void*)OUTPUT_13X13_ADDR, group_10.outputs,
       size_10 * sizeof(short));
Xil_DCacheFlushRange(OUTPUT_13X13_ADDR, size_10 * sizeof(short));

memcpy((void*)OUTPUT_26X26_ADDR, group_13.outputs,
       size_13 * sizeof(short));
Xil_DCacheFlushRange(OUTPUT_26X26_ADDR, size_13 * sizeof(short));

// Signal completion
volatile int* done_flag = (volatile int*)DONE_FLAG_ADDR;
*done_flag = 0xDEADBEEF;
Xil_DCacheFlushRange(DONE_FLAG_ADDR, sizeof(int));
```

Listing 7: DDR memory dump implementation in main.c

8.1.4 Speed Comparison

Method	Time for 216,320 values	Improvement
UART @ 115200	∼30-60 seconds	Baseline
DDR Memory Dump	∼2-3 seconds	**10-20× faster**

Table 16: Output transfer speed comparison

8.2 Memory Map Used

Address	Size	Purpose
0x00100000	∼35MB	Application code + data
0x10000000	87KB	13×13 layer output buffer
0x10100000	346KB	26×26 layer output buffer
0x10200000	4B	Completion flag
0x10300000	4B	Magic flag (FPGA ready)
0x10400000	1.4MB	Input image buffer

Table 17: DDR memory map

9 Results & Demonstration

9.1 Detection Output

```
Input Loaded
count=0
nboxes0=0
car: 90%  (l:219, r:278, t:103, b:159)
car: 52%  (l:76, r:97, t:99, b:115)
nboxes=3
End of Detection
```

9.2 Expected vs Actual Line Counts

File	Expected	Actual	Status
10.txt	43,264	43,264	✓
13.txt	173,056	173,056	✓
yolo0_cal.dat	43,095	43,095	✓
yolo1_cal.dat	172,380	172,380	✓

Table 18: Output file verification

9.3 Performance Metrics

Metric	Value
FPGA Inference Time	536.442 ms (measured)
Output Transfer (DDR)	∼2-3 sec
Post-processing Time	∼100ms
Total Pipeline	∼3-4 sec per image
Power Consumption	∼2W (FPGA only)
Energy per Inference	∼1.07 J

Table 19: Performance metrics summary

9.4 Detectable Objects (COCO 80 Classes)

The model can detect 80 object classes from the COCO dataset:

Category	**Objects**
People	person
Vehicles	bicycle, car, motorcycle, airplane, bus, train, truck, boat
Animals	bird, cat, dog, horse, sheep, cow, elephant, bear, zebra, giraffe
Outdoor	traffic light, fire hydrant, stop sign, parking meter, bench
Sports	frisbee, skis, snowboard, sports ball, kite, baseball bat, baseball glove, skateboard, surfboard, tennis racket
Food	banana, apple, sandwich, orange, broccoli, carrot, hot dog, pizza, donut, cake
Kitchen	bottle, wine glass, cup, fork, knife, spoon, bowl, microwave, oven, toaster, sink, refrigerator
Furniture	chair, couch, potted plant, bed, dining table, toilet
Electronics	tv, laptop, mouse, remote, keyboard, cell phone
Accessories	backpack, umbrella, handbag, tie, suitcase
Other	book, clock, vase, scissors, teddy bear, hair drier, toothbrush

Table 20: COCO dataset object classes

Note: YOLOv3-Tiny works best with full-body views of people and common objects. Close-up faces or partial views may not be detected reliably.

10 Lessons Learned

10.1 Technical Lessons

1. **Data Format Matters:** Neural network accelerators are extremely sensitive to input data format. A single transpose or wrong channel order causes complete failure.

2. **Quantization Awareness:** When using quantized networks, track where scaling factors are applied - both in hardware and software.

3. **Activation Functions:** Hardware implementations may apply activations (sigmoid, ReLU) internally. Applying them again in post-processing is a common bug.

4. **Memory Management:** C/C++ code must allocate memory AFTER knowing dimensions, not before.

5. **Cross-Platform Development:** Windows scripts rarely work on Linux without modification.

10.2 Debugging Strategies That Worked

1. **Compare with Expected Values:** Comparing intermediate outputs against known-good values from the research paper helped identify issues.

2. **Verify Intermediate Results:** Check tensor sizes, value ranges, and data formats at each pipeline stage.

3. **Use Memory Debuggers:** Valgrind identified the exact line causing memory corruption.

4. **Read the Source:** The HLS code revealed the sigmoid was already applied by FPGA hardware.

5. **Incremental Testing:** Test each pipeline stage independently before integration.

10.3 What We Would Do Differently

1. Create automated unit tests for each pipeline stage from the start

2. Document data formats explicitly at each stage

3. Use version control for all configuration changes

4. Set up continuous integration for the full pipeline

- COCO Dataset: Common Objects in Context (https://cocodataset.org/)

11.3 Tools Used

- Xilinx Vivado HLS 2019.2
- Xilinx Vitis IDE 2019.2
- GCC ARM Cross-Compiler
- Python 3.8+ with NumPy
- Valgrind (for memory debugging)

A File Format Specifications

A.1 group_0_input.h Format

```
#ifndef GROUP_0_INPUT_H
#define GROUP_0_INPUT_H
short layer_input[]={
128,128,128,128,  // Pixel 0: R,G,B,A (gray padding)
128,128,128,128,  // Pixel 1: R,G,B,A
...
};
#endif
```

A.2 DDR Output Format

Binary file with 16-bit signed integers (little-endian):

- `output_13x13.bin`: 43,264 values $\times$ 2 bytes = 86,528 bytes
- `output_26x26.bin`: 173,056 values $\times$ 2 bytes = 346,112 bytes

A.3 yolo*_cal.dat Format

```
0.63671875
0.43359375
0.4140625
...
```

(One float per line, Q8.8 converted to float by dividing by 256)
